* MPR (multiplanar reconstruction) - allows you to reconstruct coronal and sagittal plane as standard axial sections do not always provide sufficient information for the assessment of changes detected (eg identification of the fracture line, or visualization of the pathological relationship with the surrounding structures). The MIP (maximum intensity projection) - allows you to visualize the most dense structure with respect to adjacent less dense (such as used during intravenous contrast for the study of the blood vessels). MinIP (minimum intensity projection) - opposite MIP reconstruction technique (Example of use - Status assessment wall of the bronchus). The SSD (curvilinear

reconstruction) - allows you to display the surface of an organ or bone (a valuable method for the planning of surgery, as well as for the evaluation of the pathological process from different angles). These special imaging techniques allow comprehensive, fairly, comprehensively and clearly identify (or rule out), to interpret, as well as the display on the medium (eg film) pathological changes identified in the performance of multislice computed tomography, which ultimately allows you to choose the right tactics treatment.
